THREE-DIMENSIONAL ELASTIC-PLASTIC FINITE-ELEMENT
ANALYSIS OF FATIGUE CRACK PROPAGATION

BY

R. G. Chermahini¹ and G. L. Goglia²

INTRODUCTION

Fatigue cracks have been a major problem in designing structures subjected to cyclic loading. Cracks frequently occur in structures such as aircraft and spacecraft. The inspection intervals of many aircraft structures are based on crack-propagation lives. Therefore, improved prediction of propagation lives under flight-load conditions (variable-amplitude loading) are needed to provide more realistic design criteria for these structures.

The main thrust of this study was to develop a three-dimensional, non-linear, elastic-plastic, finite element program capable of extending a crack and changing boundary conditions for the model under consideration. The finite-element model is composed of 8-noded (linear-strain) isoparametric elements. In the analysis, the material is assumed to be elastic-perfectly plastic. The cycle stress-strain curve for the material is shown in Fig. 1. Zienkiewicz's "initial-stress" method, von Mises's yield criterion, and Drucker's normality condition under small-strain assumptions are used to account for plasticity. The three-dimensional analysis is capable of extending the crack and changing boundary conditions under cyclic loading. Initially, the crack is assumed to grow as a straight-through crack.

¹Research Associate, Department of Mechanical Engineering & Mechanics, Old Dominion University, Norfolk, VA 23508.

²Eminent Professor, Department of Mechanical Engineering & Mechanics, Old Dominion University, Norfolk, VA 23508.

Using a three-dimensional nonlinear computer program on a cyber-nos system was impossible due to its limited storage capacity. To avoid this problem, the next alternative was to utilize a VPS-32 machine with unlimited storage capacity. Using the scalar version of the program on the VPS-32 was costly due to the plasticity part of the program. Therefore, in order to reduce the cost of the computations, the three-dimensional computer program was vectorized.

The finite-element formulation of the program using an 8-noded linear isoparametric cubic element is listed in Appendix A. The description of the nonlinear program is attached in Appendix B. A list of the program is shown in Appendix C.

APPENDIX A

FINITE-ELEMENT FORMULATION

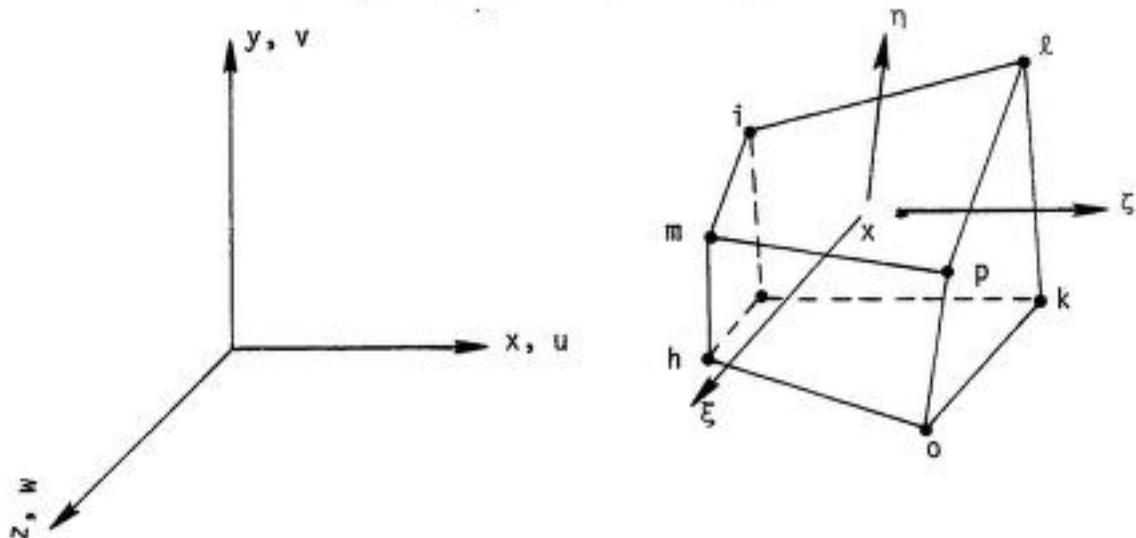

Figure 2. Arbitrary hexahedron.

(a) Elastic Analysis

The basic concept of the finite-element method is that any continuous quantity can be approximated by a discrete model composed of a set of piecewise continuous functions defined over a finite number of subdomains (1).

An isoparametric 8-noded cubic element (Fig. 2.) was utilized in the formulation of the elastic-plastic structure into the nonlinear computer program. The following section describes cubic element.

Displacement Functions. The displacement function (2) for any point in the cubic element is defined as:

$$\begin{aligned}
 u(x,y,z) &= a_1 + a_2x + a_3y + a_4z + a_5xy + a_6yz + a_7xz + a_8xyz \\
 v(x,y,z) &= b_1 + b_2x + b_3y + b_4z + b_5xy + xy + b_6yz + b_7xz + b_8xyz \\
 w(x,y,z) &= c_1 + c_2x + c_3y + c_4z + c_5xy + c_6yz + c_7xz + c_8xyz
 \end{aligned} \quad A(1)$$

where u , v and w are displacement in the x , y and z directions, respectively. The constant coefficients are determined by imposing the nodal coordinates of each cubic element into equations A (1). The above displacement function can be applied to the cubic element as long as the sides of the cubic element are defined by planes parallel to the coordinate planes. However, for the elements whose sides are skewed, the above displacement function no longer is applicable. Therefore, in order to avoid this restriction, an 8-noded linear isoparametric cubic element is employed (Fig. 2.).

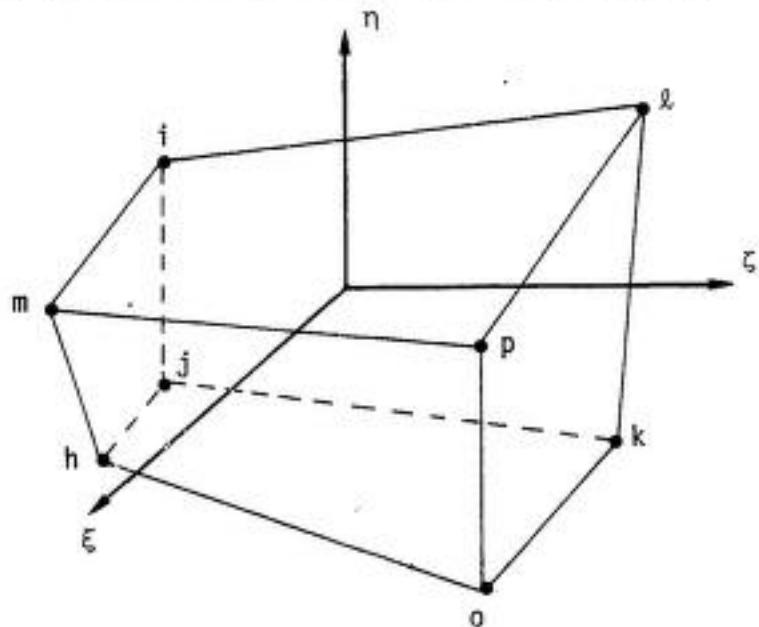

The original cube can be mapped on to a cube of $2 \times 2 \times 3$ unit (2) in the ξ , η , ζ space by the transformation

$$\begin{aligned}
 x &= a_1 + a_2\xi + a_3\eta + a_4\zeta + a_5\xi\eta + a_6\xi\zeta + a_7\eta\zeta + a_8\xi\eta\zeta \\
 y &= b_1 + b_2\xi + b_3\eta + b_4\zeta + b_5\xi\eta + b_6\xi\zeta + b_7\eta\zeta + b_8\xi\eta\zeta \\
 z &= c_1 + c_2\xi + c_3\eta + c_4\zeta + c_5\xi\eta + c_6\xi\zeta + c_7\eta\zeta + c_8\xi\eta\zeta
 \end{aligned} \quad A(2)$$

The values of the coefficients in equation A(2) depend on the nodal coordinates of each cubic element and are different for different elements. The transformation is defined by polynomials in ξ , η and ζ which is continuous within the element, the continuum confined within an element in x , y and z coordinates is mapped on to a continuum within the $2 \times 2 \times 2$ cube in ξ , η and ζ coordinates. It remains to be shown that the transformation is continuous across two adjoined elements, that a common surface between

two adjoined elements in the x , y , z space will transform into a common surface of two adjoined cubes in ξ , η , ξ space.

If we assign the following values of the parameters ξ , η , ξ to the faces of distorted elements shown in (Fig. 3.) one yields:

<u>Face</u>	<u>Coordinate value</u>
pokl	$\xi = 1$
mnji	$\xi = 1$
impl	$\eta = 1$
jnok	$\eta = -1$
mnop	$\xi = 1$
ijkl	$\xi = 1$

Fig. 3. Linear isoparametric cubic element.

Therefore, the nodal points i, j, k, l and m, n, o, p will have the following coordinates in the ξ , η , ξ :

nodal point		coordinates	
i	$\xi_i = -1$	$\eta_i = 1$	$\xi_i = -1$
j	$\xi_j = -1$	$\eta_j = -1$	$\xi_j = -1$
k	$\xi_k = 1$	$\eta_k = -1$	$\xi_k = -1$
l	$\xi_l = 1$	$\eta_l = 1$	$\xi_l = -1$
m	$\xi_m = -1$	$\eta_m = 1$	$\xi_m = 1$
n	$\xi_n = -1$	$\eta_n = -1$	$\xi_n = 1$
o	$\xi_o = 1$	$\eta_o = -1$	$\xi_o = 1$
p	$\xi_p = 1$	$\eta_p = 1$	$\xi_p = 1$

Now the displacements (u , v , w) in the x , y , z directions can be written as:

$$\begin{aligned} u &= \alpha_1 + \alpha_2\xi + \alpha_3\eta + \alpha_4\xi + \alpha_5\xi\eta + \alpha_6\eta\xi + \alpha_7\xi^2 + \alpha_8\xi\eta\xi \\ v &= \beta_1 + \beta_2\xi + \beta_3\eta + \beta_4\xi + \beta_5\xi\eta + \beta_6\eta\xi + \beta_7\xi^2 + \beta_8\xi\eta\xi \\ w &= \gamma_1 + \gamma_2\xi + \gamma_3\eta + \gamma_4\xi + \gamma_5\xi + \gamma_6\eta\xi + \gamma_7\xi^2 + \gamma_8\xi\eta\xi \end{aligned} \quad A(3)$$

which are continuous (2) within the elements as well as across the surfaces common to any two adjoined elements. Consider the term u in equations A(3), denote by $\{a\}$ and $\{U\}$ the vectors for the α 's and u_i nodal displacements of all the nodal points of the element. Inserting the values of u_i , ξ_i , η_i and ξ_i for the various nodal points, we obtain eight equations corresponding to the first equation of A(3) which can be written as

$$\{U\} = [A_1] \{a\} \quad A(4)$$

Let's define $[\alpha_1] = [A_1]$, and thus have $\{a\} = [\alpha_1] \{u\}$. Now the displacement functions for the distorted element can be written as:

$$\begin{aligned} u &= [S] [\alpha_1] \{u\} \\ v &= [S] [\alpha_1] \{v\} \\ w &= [S] [\alpha_1] \{w\} \end{aligned} \quad A(5)$$

where $[S]$ is defined as:

$$[S] = [1 \ \xi \eta \xi \eta \xi \eta \xi \eta \xi] \quad A(6)$$

The shape functions for the isoparametric 8-noded element can be determined
 (1) from the product of $[S]$ and $[\alpha_1]$ matrices.

$$N_i = \frac{1}{8} (1+\xi_i) (1+\eta_i) (1+\zeta_i) \quad A(7)$$

where $\xi_i, \eta_i, \zeta_i = \pm 1$ and $i = 1, 2, \dots, 8$.

The x , y , and z coordinates at any point in the element, can be expressed in terms of shape functions N_i :

$$\begin{aligned} x &= \sum_{i=1}^8 N_i x_i \\ y &= \sum_{i=1}^8 N_i y_i \\ z &= \sum_{i=1}^8 N_i z_i \end{aligned} \quad A(8)$$

or

$$\begin{Bmatrix} x \\ y \\ z \end{Bmatrix} = \begin{Bmatrix} [N] & [0] & [0] \\ [0] & [N] & [0] \\ [0] & [0] & [N] \end{Bmatrix} \begin{Bmatrix} \{x_n\} \\ \{y_n\} \\ \{z_n\} \end{Bmatrix}$$

where $\{x_n\}^T = [x_1 \ x_2 \ \dots \ x_8]$, $\{y_n\}^T = [y_1 \ y_2 \ \dots \ y_8]$

and $\{z_n\}^T = [z_1 \ z_2 \ \dots \ z_8]$.

Element Strain: The elastic strain at any point within the element is given by [3]

$$\{\varepsilon\} = \begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_z \\ \gamma_{xy} \\ \gamma_{yz} \\ \gamma_{zx} \end{Bmatrix} = \begin{Bmatrix} \frac{\partial u}{\partial x} \\ \frac{\partial v}{\partial y} \\ \frac{\partial w}{\partial z} \\ \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \\ \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \\ \frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \end{Bmatrix} = [\mathbf{B}_1 \ \mathbf{B}_2 \ \dots \ \mathbf{B}_8] \ \{u\} = [\mathbf{B}] \ \{u\} \quad A(9)$$

where the matrix $[\mathbf{B}]$ is defined as:

$$\left[\begin{array}{ccc} \frac{\partial N_i}{\partial x} & 0 & 0 \\ 0 & \frac{\partial N_i}{\partial y} & 0 \\ 0 & 0 & \frac{\partial N_i}{\partial z} \end{array} \right] = [B_i] = \left[\begin{array}{ccc} \frac{\partial N_i}{\partial x} & \frac{\partial N_i}{\partial y} & 0 \\ \frac{\partial N_i}{\partial y} & \frac{\partial N_i}{\partial z} & \frac{\partial N_i}{\partial x} \\ 0 & \frac{\partial N_i}{\partial z} & \frac{\partial N_i}{\partial y} \\ \frac{\partial N_i}{\partial z} & 0 & \frac{\partial N_i}{\partial x} \end{array} \right] \quad A(10)$$

The transformation relationship between local and global coordinates is given by:

$$\left\{ \begin{array}{c} \frac{\partial N_i}{\partial x} \\ \frac{\partial N_i}{\partial y} \\ \frac{\partial N_i}{\partial z} \end{array} \right\} = [J]^{-1} \left\{ \begin{array}{c} \frac{\partial N_i}{\partial \xi} \\ \frac{\partial N_i}{\partial \eta} \\ \frac{\partial N_i}{\partial \zeta} \end{array} \right\} \quad A(11)$$

where $[J]$ is the Jacobian matrix and it is defined as:

$$[J] = \left[\begin{array}{c} \frac{\partial \{N\}}{\partial \xi}^T \\ \frac{\partial \{N\}}{\partial \eta}^T \\ \frac{\partial \{N\}}{\partial \zeta}^T \end{array} \right] \{x_n\} \{y_n\} \{z_n\} \quad A(12)$$

where $\{x_n\}^T = [x_1 \ x_2 \ \dots \ x_6]$.

Element Stress. For linear-elastic and isotropic materials, the element stresses are calculated using Hook's law

$$\{\sigma\} = [D] \{\epsilon\} + \{\delta\} \quad A(13)$$

The strain vector is $\{\epsilon\} = [B] \{u\}$; therefore, the stresses are

$$\{\sigma\} = [D] [B] \{u\} + \{\delta\} \quad A(14)$$

where $\{\sigma^0\}$ is initial stress which may exist in the element. The material property matrix $[D]$, is defined as:

$$[D] = \frac{E}{(1+v)(1-2v)} \begin{vmatrix} 1-v & v & v & 0 & 0 & 0 \\ v & 1-v & v & 0 & 0 & 0 \\ v & v & 1-v & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1-2v}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1-2v}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1-2v}{2} \end{vmatrix} \quad A(15)$$

where E is Young's modulus and v is poisson's ratio for the material.

Element Equations. The potential energy π_p (u, v, w) which is composed of strain energy u_p (u, v, w) and v_p (u, v, w) the work done by the applied loads during displacement changes is given by [3].

$$\pi_p = \frac{1}{2} \iiint_V \{\epsilon\}^T [D] \{\epsilon\} dv - \iiint_V [F^*] \{\delta\} dv + \iint_{S_1} [T^*] \{\delta\} ds \quad A(16)$$

$$\text{where } [F^*] = [x^* y^* z^*], [T^*] = [T_x^* T_y^* T_z^*].$$

$$\text{and } [\delta] = [u, v, w].$$

The equilibrium equations for the element are obtained by taking partial derivatives of π_p with respect to u_1, v_1, w_1 , etc., and equating to zero,

$$\frac{\partial \pi_p}{\partial \{u\}} = 0, \quad A(17)$$

which leads to the 24 element equilibrium equations as

$$[K] \{u\} = \{q\} = \{q_1\} + \{q_2\} \quad A(18)$$

24x24	24x1	24x1	24x1	24x1
-------	------	------	------	------

where $[K]$ is the element stiffness matrix,

$$[k] = \iiint_V [B]^T [D] [B] dv + [K_s] \quad A(19)$$

and $\{Q\}$ is the element nodal load vector,

$$\{Q\} = \{Q_1\} + \{Q_2\} = \iiint_V [N]^T \{F^*\} dv + \iint_{S_1} [N]^T \{T^*\} ds \quad A(20)$$

The diagonal matrix $[K_s]$ in Eq. A(19) is the eleastic stiffness of the springs, which are connected to the boundary nodes.

(b) Elastic-plastic analysis

Finite-element techniques applied to linear elastic materials have been solved successfully. However, for an elastic-plastic material, the coefficient in the stiffness matrix varies as a function of material loading. Two computational methods have been used successfully in the solution of elastic-plastic problems. In the first, the change at each step of load increase in plastic strain is calculated and treated as an initial strain for which the elastic stress distribution is adjusted (1). This method fails if ideal plastic is postulated or if the degree of hardening is small. In the second method, the "incremental stress method," the stress-strain relationship for every load increment is adjusted to account for plastic deformations. The work of Pope (4), Swedlow (5), Marcal and King (6), Reyes and Deere (7) and Popov and others (8) falls into this category.

The "incremental elasticity" method has one serious disadvantage. At each step of the computation the stiffness matrix of the structure is updated and iterative schemes of solution are necessary to avoid excessive computational costs. To minimize computational costs, the "initial stress" approach is used (1). In the incremental stress method, the basic elasticity matrix remains unchanged. This technique converges more rapidly than the initial strain method.

Yield Criterion. In any elastic-plastic analysis, it is necessary to introduce a yield criterion to determine the state of stress at which yielding

occurs. The von Mises yield criterion or maximum distortion energy theory of failure, which finds considerable experimental support in ductile materials, is used to determine whether the material at any point in the structure has yielded. This criterion assumes that yielding begins when the distortion energy equals the distortion energy at yield in simple tension (1). The von Mises yield criterion for a three dimensional state of stress is given by

$$F = F(\sigma) = \left[\frac{1}{2} (\sigma_x - \bar{\sigma})^2 + \frac{1}{2} (\sigma_y - \bar{\sigma})^2 + \frac{1}{2} (\sigma_z - \bar{\sigma})^2 + 3T_{xy}^2 + 3T_{xz}^2 + 3T_{yz}^2 \right]^{\frac{1}{2}} - \bar{\sigma} \quad A(21)$$

where $\bar{\sigma} = \sigma(K)$ is the uniaxial stress at yield. If $F(\sigma) < 0$, the material is in elastic range. If $F(\sigma) > 0$, the material has experienced plastic deformation and one of the flow theories of plasticity must be used for determining the components of plastic strains and stresses due to the applied load.

During an infinitesimal increment of stress, changes of strain are assumed to be divisible into elastic and plastic parts (1). Thus, the strain increment can be written as:

$$\{\delta e\} = \{\delta e_e\} + \{\delta e_p\} \quad A(22)$$

where the elastic strain increments are related to the stress increments by the symmetric material matrix D . The plastic strain increments are related

to the yield criterion through Drucker's normality principle

$$\{d\epsilon_p\} = \lambda \left\{ \frac{\partial F}{\partial \sigma} \right\} \quad A(23)$$

Therefore; Eq. A(22) can be rewritten as:

$$\{d\epsilon\} = [D]^{-1} \{d\sigma\} + \lambda \left\{ \frac{\partial F}{\partial \sigma} \right\} \quad A(24)$$

At the point of incipient plasticity, the stresses are on the yield surface and the yield function is given by:

$$F(\sigma, k) = 0 \quad A(25)$$

where K is a hardening parameter.

Differentiating A(25) results in:

$$d_F = \frac{\partial F}{\partial \sigma_1} d\sigma_1 + \frac{\partial F}{\partial \sigma_2} d\sigma_2 + \dots + \frac{\partial F}{\partial k} dk = 0 \quad A(26)$$

$$\text{or } \left\{ \frac{\partial F}{\partial \sigma} \right\} T d\sigma - A \lambda = 0 \quad A(27)$$

Solving for A gives

$$A = - \frac{\partial F}{\partial k} dk \frac{1}{\lambda} \quad . \quad A(28)$$

Equations A(24) and A(27) can be written in matrix form as

$$\begin{Bmatrix} d\epsilon \\ 0 \end{Bmatrix} = \begin{bmatrix} D^{-1} & \frac{\partial F}{\partial \sigma} \\ \left(\frac{\partial F}{\partial \sigma}\right)^T & -A \end{bmatrix} \begin{Bmatrix} d\sigma \\ \lambda \end{Bmatrix} \quad A(29)$$

The constant λ can be eliminated from Eq. A(23). The final expression which relates the stress changes in terms of imposed strain changes can be written as: $d\sigma = D_{ep}^* d\epsilon$

A(30)

or

$$D_{ep}^* = D - D \left\{ \frac{\partial F}{\partial \sigma} \right\} \left\{ \frac{\partial F}{\partial \sigma} \right\}^T D \left[A + \left\{ \frac{\partial F}{\partial \sigma} \right\}^T D \left\{ \frac{\partial F}{\partial \sigma} \right\} \right]^{-1} \quad A(31)$$

where $\left\{ \frac{\partial F}{\partial \sigma} \right\}^T = [F_x \ F_y \ F_z \ F_{xy} \ F_{yz} \ F_{xz}]$

and $F_x = \frac{3\sigma_1}{2\bar{\sigma}}, \quad F_y = \frac{3\sigma_2}{2\bar{\sigma}}, \quad F_z = \frac{3\sigma_3}{2\bar{\sigma}}$

$$F_{xy} = \frac{3T_{xy}}{\bar{\sigma}}, \quad F_{yz} = \frac{3T_{yz}}{\bar{\sigma}}, \quad F_{zx} = \frac{3T_{zx}}{\bar{\sigma}} \quad A(32)$$

in which the dashes stand for deviatoric stresses i.e.

$$\sigma_1 = \sigma_x - \frac{(\sigma_x + \sigma_y + \sigma_z)^0}{3} \text{ etc.}$$

The elastic-plastic matrix D_{ep}^* replaces the elastic matrix D in incremental elastic-plastic analysis. The plastic load vector for the elements which deform plastically is given by:

$$\{dq\} = \iiint [B]^T \{\dot{d\sigma}\} dv_m \quad A(33)$$

where $\{\dot{d\sigma}\}$ is defined as:

$$\{\dot{d\sigma}\} = \{d\sigma_e\} - \{d\sigma\} + ([De] - [Dep]) \{de\} \quad A(34)$$

APPENDIX B

Description of the Finite-Element Computer Program

The computer program presented here was based on the three-dimensional 8-noded linear isoparametric cubic element. The optimum goal of this study was to develop a three-dimensional nonlinear computer program capable of extending a crack and changing the boundary conditions for the model under consideration. This program in its present form is not a general analysis program for nonlinear cracked structures. The restrictions are listed as follows: (1) the crack must lie on the x-axis and propagate in the positive x-direction, (2) the configuration and loading must be symmetric about the x-axis.

The input to the program is illustrated by using one eighth of a center-crack panel shown in Fig. 4.

1. CRACK, WIDTH, THICK, HEIGHT, DAX:, SCALE (6E10.4)

The format for each input is shown in parenthesis. Crack specifies the crack length in the $y=0$ plane. Width, thick, height represent width, thickness and height of the structure., DAX is defined as the smallest element size in the region and is used for the crack-extension in the program. Scale, scales the width, thickness and height of the specimen to the desired dimension.

2. LPRIT, LMAX, KMAX, NLAYER, NEP (1615)

LPRIT = 0 indicates that no intermediate output is printed. LPRIT = 1 results in intermediate output. LMAX is the number of nodes in $Z=0$ plane. KMAX is the number of elements in $Z=0$ plane. NLAYER indicates the number of layers in the structure. NEP specifies elastic or

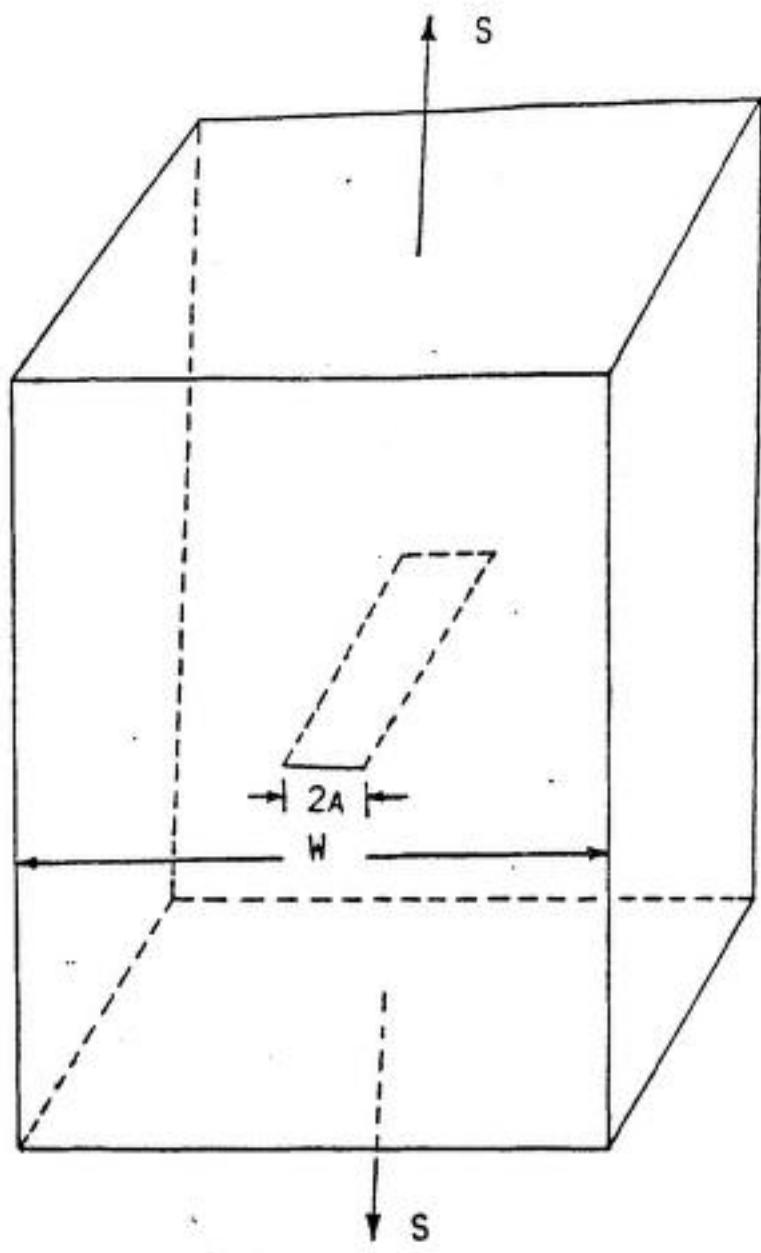

Figure 4. Center-Crack Panel subjected to uniform stress.

- plastic analysis if NEP=0, elastic analysis is performed. If NEP > 0, the plastic analysis is performed.
3. K, XR(I), YR(I), ZR(I), (I5, 4X , 3 E15.7)
K refers to the node number, and XR(I), YR(I), ZR(I) are the coordinates of node K in x,y and z direction, respectively.
 4. IN, (MODE(J, IN), J = 1,8) (1615)
IN describes the element number, and node gives the nodal connective of each cubic element in the structure.
 5. NSYMPL (1615)
NSYMPL specifies the number of symmetric planes
 6. (ISYMPY(I), I = 1, NYSMPL) (1615)
ISYMPY describes the corresponding numbers designated for each plane in the structure.
 7. NFIX, NLOAD, SNPD (1615)
NFIX, NLOAD NSPD describe the number of fixed loaded, and specified displacements for nodes, respectively.
 8. NODF, MU, MV, MW (1615)
NODF describes the number of fixed nodes, and MU, MV and MW represents the u, v and w displacements fixed for each node.
 9. Nodlod (IL), Px, Py, Pz (1615)
Nodlod specifies the number of loaded nodes, and Px, Py and Pz represent the components of loading in x, y, and z direction, respectively.
 10. NODS, K, DISP(N) (1615)
NODS is the node number, K is the code for u, v and w

displacements, and Disp is the specified displacement for the corresponding node.

11. NTYP, NLM, SCRIT, RP, ACURCY (215, 4E10.4)

NTYP stands for the crack growth criterion. NLM is the number of increments to release the crack tip force. SCRIT is used for the CTOD criterion. RP is the relaxation parameter and ACURCY is used for the crack opening displacement accuracy.

12. P, WORD (E103, 1X, A₄)

P designates the maximum applied stress for each cycle. The word specifies stationary or growing crack for each cycle. If word is set equal to grow, the crack will extend one element size. If word is equal to halt, the crack will be stationary for that cycle.
